

Ice Task 4

ST10440289

Even though SQL and NoSQL both work with data, they are not the same and have major differences. They make it simple to create, read, update, or delete data while also including indexing, security, and data backup or replication. (GeeksforGeeks, 2025) (IBM, 2025)

SQL databases, which are relational, are organized in tables using rows and columns and operate with a set structure. They are perfect for any software that needs regular updates and expansions, including banking, shopping, or stock keeping. These databases are among the most common, which are MySQL, PostgreSQL, and Microsoft SQL Server. (GeeksforGeeks, 2025) (IBM, 2025)

NoSQL databases have flexible structures such as documents, key-value pairs, or graphs. NoSQL databases are suited for keeping vast quantities of unorganized or semi-organized data, and they are commonly used in real-time web applications, Internet of Things systems, or on social media. There are document stores such as MongoDB, key-value stores known as Redis, and column stores like Cassandra in NoSQL. (GeeksforGeeks, 2025) (IBM, 2025)
